

ABSTRACT OF THE DISCLOSURE

The present invention features a method for performing an end-to-end data path integrity check in a computer or computer-like system such as a storage router. A predetermined data test pattern is stored in a memory and then transmitted across a data path by a data initiator to a data receiver. The received data test pattern is then retransmitted to the data initiator where it is compared to the original data. Any discrepancies cause an error condition to be declared. The data path may be disabled until the defective component in the data path is isolated and fixed. The method is hardware independent so it may be easily used in an open systems environment where hardware components may be provided by different vendors.
